## 1.1 Sparsity Condition 1

Assume that there is a mapping  $L : (i, j) \mapsto \{0, 1\}$ , representing the “locations” of large elements. For  $L_{ij} := L(i, j) = 1$  or  $0$ , the sparsity condition are different, i.e.,

$$\sum_j^p |\sigma_{ij}|^{q_0} \mathbf{1}_{L_{ij}=0} < c_0(p)$$

and

$$\sum_j^p |\sigma_{ij}|^{q_1} \mathbf{1}_{L_{ij}=1} < c_1(p)$$

where  $c_0(p), c_1(p) \rightarrow \infty$  as  $p \rightarrow \infty$ , but might have different rate of divergence. The belief is when  $L_{ij} = 1$ , although  $\sigma_{ij}$  might be large, the number of such  $\sigma_{ij}$  must be small, so the sparsity condition can hold with a smaller  $q$ . Although there potentially are many  $L_{ij} = 0$ , but each  $\sigma_{ij}$  will be small, and hence we can allow a relatively large  $q$ .

Then following Bickel, consider a hard thresholding estimator with adaptive thresholds,

$$T_{t,L}(\sigma_{ij}) = \begin{cases} \sigma_{ij} & \text{if } \sigma_{ij} > t_1 \text{ and } L_{ij} = 1 \\ \sigma_{ij} & \text{if } \sigma_{ij} > t_0 \text{ and } L_{ij} = 0 \\ = 0 & \text{otherwise} \end{cases}$$

In practice we might estimate  $L$  with  $\hat{L}$ , We have the decomposition:

$$\left\| T_{t,\hat{L}}(\hat{\Sigma}) - \Sigma \right\| \leq \left\| T_{t,\hat{L}}(\Sigma) - \Sigma \right\| + \left\| T_{t,\hat{L}}(\hat{\Sigma}) - T_{t,\hat{L}}(\Sigma) \right\| = \mathbf{I} + \mathbf{II}$$

The first term  $\mathbf{I}$  can be bounded by the  $L^1$  norm,

$$\mathbf{I} \leq \max_i \sum_j^p |\sigma_{ij}| \left( \hat{L}_{ij}^0 \mathbf{1}_{|\sigma_{ij}| \leq t_0} + \hat{L}_{ij}^1 \mathbf{1}_{|\sigma_{ij}| \leq t_1} \right)$$

where  $L_{ij}^0 := \mathbf{1}_{L_{ij}=0}$ , the location where  $L_{ij} = 0$ .

$$\begin{aligned}
\mathbf{I} &\leq \max_i \sum_j |\sigma_{ij}| \left( L_{ij}^0 \mathbf{1}_{|\sigma_{ij}| \leq t_0} + L_{ij}^1 \mathbf{1}_{|\sigma_{ij}| \leq t_1} \right) + \max_i \sum_j |\sigma_{ij}| \left( \mathbf{1}_{|\sigma_{ij}| \leq t_0} (\hat{L}_{ij}^0 - L_{ij}^0) \right) \\
&\quad + \max_i \sum_j |\sigma_{ij}| \mathbf{1}_{|\sigma_{ij}| \leq t_1} (\hat{L}_{ij}^1 - L_{ij}^1) \\
&= \mathbf{I}_1 + \mathbf{I}_2 + \mathbf{I}_3
\end{aligned}$$

Assume that for all  $i$ ,  $\sum_j |\hat{L}_{ij}^0 - L_{ij}^0| = O_p(k_n)$ . Then we have

$$\mathbf{I} \lesssim t_0^{1-q_0} c_0 + t_1^{1-q_1} c_1 + \mathbf{I}_2 + \mathbf{I}_3$$

For  $\mathbf{I}_2$ , we have

$$\mathbf{I}_2 = \max_i \sum_j |\sigma_{ij}| \left( \mathbf{1}_{|\sigma_{ij}| \leq t_0} (\hat{L}_{ij}^0 - L_{ij}^0) \right) \lesssim t_0^{1-q_1} c_1(p) k_n$$

and for  $\mathbf{I}_3$  we have,

$$\mathbf{I}_3 = \max_i \sum_j |\sigma_{ij}| \left( \mathbf{1}_{|\sigma_{ij}| \leq t_1} (\hat{L}_{ij}^1 - L_{ij}^1) \right) \lesssim t_1^{1-q_0} c_0(p) k_n$$

Hence,  $\mathbf{I} \lesssim c_1(t_1^{1-q_1} + k_n t_0^{1-q_1}) + c_0(t_0^{1-q_0} + k_n t_1^{1-q_0})$ .

For Item II, we can decompose it like in Bickel and Levina, which will give terms  $O_p(c_1 t_1^{q_1} \sqrt{\log p/n} + c_0 t_0^{q_0} \sqrt{\log p/n})$

The thing is that if  $k_n = o(1)$ , both  $t_1, t_0$  are of order  $\sqrt{\log p/n}$ .

## 1.2 Sparsity Condition 2

Suppose we don't shrink the  $\hat{\sigma}_{ij} \hat{L}_{ij}^1$ . And put conditions where  $q_1 = 0$ , i.e., like banding but with estimated locations, then
